ing a Static Website on AWS EC2

Student: Ayusha Rajput
Date: 28 October 2026
Repository: Ayusha-hub/CSA--Unit3_assignment

1. Objective

Host a static website and record the page that is served after the site is executed. The project page is a single HTML file. This report documents the files in the repository, the execution of that page, and the screenshot taken from the running site.

2. Project files

The extracted project contains:

- **index.html** — the static page that is served to the browser.
- **README.md** — the guide for launching an Amazon EC2 instance and hosting this page with Apache.
- **LICENSE** — the project license.
- **.github/FUNDING.yml** — repository funding metadata from the original project.

3. Website source

The page served during execution is the repository file **index.html**:

```
<html>
<head>
    <title>My First AWS Website</title>
</head>
<body>
    <h1>Hello, World!</h1>
    <p>Welcome to my website hosted on AWS EC2!</p>
</body>
</html>
```

4. Execution

The site was started from the project folder and opened in a browser. The server answered with HTTP 200 and returned the HTML above.

Command:

```
python -m http.server 8765
```

Address opened in the browser:

```
http://127.0.0.1:8765/
```

Response captured during execution:

```
HTTP/1.0 200 OK
Server: SimpleHTTP/0.6 Python/3.12.10
```

```
Date: Wed, 28 Oct 2026 08:54:57 GMT
Content-type: text/html
Content-Length: 173
Last-Modified: Wed, 28 Oct 2026 08:43:58 GMT
```

The browser showed the heading **Hello, World!** and the sentence **Welcome to my website hosted on AWS EC2!**

5. Screenshot after execution

Figure 1 is the browser view of the running website.

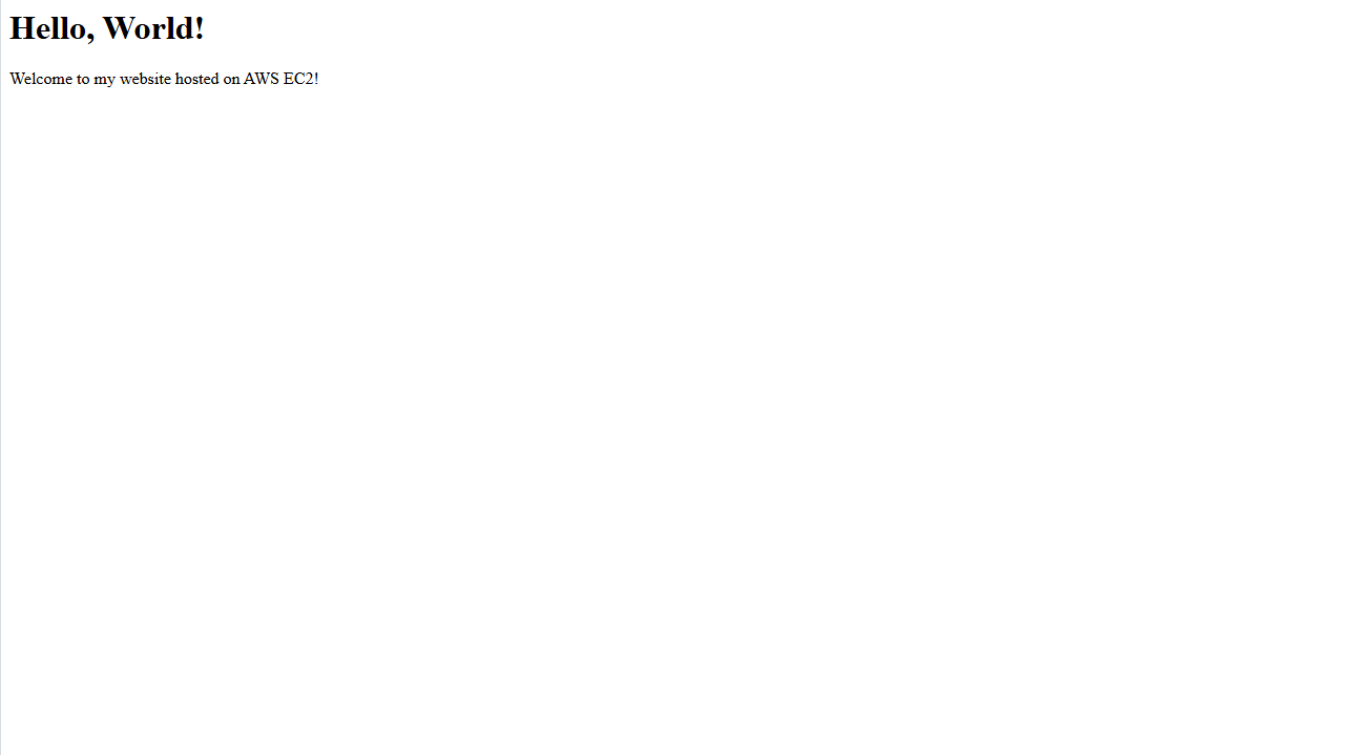

Figure 1. Static website after execution at http://127.0.0.1:8765/

The page title in the browser was My First AWS Website. No extra styling is applied in index.html, so the browser uses its default heading and paragraph layout.

6. AWS EC2 hosting procedure

The same page is intended to be hosted on an Amazon EC2 instance. The AWS CLI is not installed on this computer, so an EC2 instance was not launched here. The repository README is the deployment procedure. The steps are:

- Launch an Amazon Linux 2 instance of type t2.micro and open HTTP port 80 and SSH port 22 in the security group.
- Connect with the EC2 key pair: `ssh -i key-pair.pem ec2-user@public-dns`
- Install and start Apache: `sudo yum install -y httpd`, then `sudo systemctl enable --now httpd`.
- Copy index.html to `/var/www/html/index.html` and set permissions to 644.
- Open `http://public-dns` in a browser. The same Hello, World! page should appear.

An optional `deploy_website.sh` script in the README repeats the Apache install and writes the HTML file on the instance.

7. Result

Execution of the project website succeeded. The local server returned HTTP 200, and the browser displayed the expected heading and welcome sentence. That result is the screenshot in Figure 1. Hosting that same file on EC2 follows the Apache steps in Section 6 and in README.md.
